Question 1: Optimization: Gradient Descent and EM (40 points)

Consider a probabilistic mixture model which is defined over three binary variables X , Y and Z where Z is the mixture variable. Assume that each variable (including Z) takes values from the domain $\{0, 1\}$. The mixture model thus has two components, one corresponding to $Z = 0$ and the other corresponding to $Z = 1$. We will assume that the model makes the following assumptions:

$$P(X, Y|Z = 0) = P(X|Z = 0)P(Y|Z = 0) \text{ and } P(X, Y|Z = 1) = P(X|Z = 1)P(Y|Z = 1)$$

and has the following parameters:

$$\begin{aligned} P(Z = 0) &= \alpha \\ P(X = 0|Z = 0) &= \beta_0 \\ P(X = 0|Z = 1) &= \beta_1 \\ P(Y = 0|Z = 0) &= \lambda_0 \\ P(Y = 0|Z = 1) &= \lambda_1 \end{aligned}$$

Assume that you are given the following dataset having m examples.

$$\{(x^{(1)}, y^{(1)}), \dots, (x^{(m)}, y^{(m)})\}$$

Your task in this question is to derive a gradient descent algorithm for computing the maximum likelihood estimates of the parameters α , β_0 , β_1 , λ_0 and λ_1

- (a) (10 points) Write the expression for log-likelihood of the data. (Note that Z is a hidden variable).

- (b) (10 points) Compute the gradient of the log-likelihood w.r.t. the parameters α , β_0 , β_1 , λ_0 and λ_1 and write down the expressions below:

Gradient w.r.t. α =

Gradient w.r.t. β_0 =

Gradient w.r.t. β_1 =

Gradient w.r.t. $\lambda_0 =$

Gradient w.r.t. $\lambda_1 =$

EM Algorithm. In this part, your task is to estimate the parameters α , β_0 , β_1 , λ_0 and λ_1 using the EM algorithm.

- (c) (10 points) Recall that in the E-Step, we complete the data and then assign a weight (conditional probability) to each possible completion of each example. Consider an arbitrary example $(x^{(j)}, y^{(j)})$. This example can be completed in two ways: $(x^{(j)}, y^{(j)}, Z = 0)$ and $(x^{(j)}, y^{(j)}, Z = 1)$. Let f_{j0} and f_{j1} be the weights assigned to $(x^{(j)}, y^{(j)}, Z = 0)$ and $(x^{(j)}, y^{(j)}, Z = 1)$ respectively. Write down the precise expression for f_{j0} and f_{j1} such that $f_{j0} + f_{j1} = 1$ in terms of the current parameters: α , β_0 , β_1 , λ_0 and λ_1 .

- (d) (10 points) Recall that in the M-step, we update the parameters such that they maximize the log-likelihood of the weighted data. In this question, you will derive and write down the expressions for the following new or updated parameters (you can use f_{j0} and f_{j1} defined in part (a) to simplify notation):

new $\alpha =$

new $\beta_0 =$

new $\beta_1 =$

new $\lambda_0 =$

new $\lambda_1 =$

Question 2: Learning Theory (20 points)

Recall that for hypothesis class H , its VC dimension is greater than or equal to k if there exists a set S of k data points, namely $|S| = k$, which is shattered by H .

- (a) (5 points) Consider the class of concepts that can be expressed as an axis parallel rectangle. Assume further that the rectangles can be defined in terms of 4 integers: a , b , c , and d that lie between 1 and 100 (both included). Namely, $a, b, c, d \in \{1, \dots, 100\}$. We assume that a consistent algorithm is available.
- What is the size of the hypothesis space.

- How many randomly obtained examples are needed for PAC learning with accuracy parameter $\epsilon = 0.1$ and confidence parameter $\delta = 0.05$?

- What is the accuracy level (what is ϵ) if it is known that 1000 randomly chosen examples were used, and the desired confidence level is $\delta = 0.05$?

- (b) (5 points) Let $x \in \mathbb{R}^2$ (2-dimensional reals), H is the set of axis-parallel squares (equal height and width). Find the largest k such that the VC dimension of H is greater than or equal to k .

- (c) (5 points) Let $x \in \mathbb{R}$ (1-dimensional reals), H is the set of functions defined as follows: $H(x) = \text{sign}(ax^2 + bx + c)$ where a, b and c are real numbers and are parameters in H , $\text{sign}(x) = +1$ if $x \geq 0$ and $\text{sign}(x) = -1$ otherwise. Find the largest k such that the VC dimension of H is greater than or equal to k .

- (d) (5 points) H is a finite hypothesis class such that $|H| < \infty$ where $|H|$ is the size of H . Show that the VC dimension of H is upper bounded by $\log_2 |H|$.

Question 3: Bayesian networks: Variable Elimination (20 points)

Consider the Bayesian network given below:

- (a) (7 points) Show the steps in the variable elimination algorithm for computing $P(X_9 = x_9)$ along the ordering $(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8)$.

- (b) (3 points) What is the time and space complexity of variable elimination along the ordering given above? Assume that each variable has d values in its domain.

- (c) (5 points) Consider a Bayesian network defined over a set of Boolean variables $\{X_1, \dots, X_n\}$. Assume that the number of parents of each node is bounded by a constant. Then, the probability $P(X_i = \text{True})$ for any arbitrary variable $X_i \in \{X_1, \dots, X_n\}$ can be computed in polynomial time (namely, in $O(n^k)$ time, where k is a constant). True or False. Explain your answer. No credit without correct explanation.
- (d) (5 points) Let $\{X_1, \dots, X_r\}$ be a subset of root nodes of a Bayesian network (the nodes having no parents). Then, $P(X_1 = x_1, \dots, X_r = x_r) = \prod_{i=1}^r P(X_i = x_i)$ where the notation $X_j = x_j$ denotes an assignment of value x_j to the variable X_j , $1 \leq j \leq r$. True or False. Explain your answer. No credit without correct explanation.

Question 4: Hidden Markov Models (10 points)

- (a) (10 points) Recall that a HMM makes a 1-Markov assumption, i.e., the state variable X_t is conditionally independent of $X_{1:t-2}$ given X_{t-1} . Consider a HMM that makes a 2-Markov assumption instead, i.e., the state variable X_t is conditionally independent of $X_{1:t-3}$ given $\{X_{t-1}, X_{t-2}\}$. Describe in your own words how the filtering algorithm for this 2-Markov HMM will be different from the filtering algorithm for HMMs (you don't have to provide a pseudo code). Also, compare the time and space complexity of the 2-Markov HMM filtering algorithm with 1-Markov HMM filtering algorithm. What will be the computational complexity of filtering if we make a k -Markov assumption instead, where $k > 2$?

Question 5: Clustering (10 points)

- (a) (5 points) Starting with two cluster centers indicated by squares, perform k-means clustering on the following data points (denoted by \times). In each panel, indicate the data assignment and in the next panel show the new cluster means. Stop when converged or after 6 steps whichever comes first. Use Euclidean distance as the distance measure.

- (b) (5 points) Do single link clustering and complete link clustering have the same computational complexity. Explain your answer. No credit will be given without a correct explanation.
